- Interrupts normal sequencing of the processor
- Provided to improve processor utilization
  - I/O devices are slower than CPU
  - Without interrupts, CPU must pause to wait for device (wastes its time)
- Interrupts ensure timely process switches
- Interrupts provide user access to potentially dangerous instructions

### Interrupts- where in instruction cycle

- Fetch & Execute & Interrupt
  - Same as before, plus an Interrupt Stage

### Interrupts-types

- Types
- Hardware
  - Raised by hardware devices
  - Can occur at any time (Asynchronous)
  - Examples: timer (process switch), I/O signals
- Traps:
  - Software interrupts (Synchronous)
  - Raised by user programs to invoke OS functionality
- Exceptions
  - Generated by processor as a result of illegal action (Synchronous)
  - Faults: recoverable (page fault)
  - Aborts: difficult to recover (divide by 0)

### **But First:**

### Kernel Mode verses User Mode

#### Kernel Mode

- Most privileged
- Access to entire file system, memory space, all hardware
- OS runs as this

#### User Mode

- Least privileged
- Access to resources (like files and memory) that belong to current user
- User processes run as this

#### How to verify access?

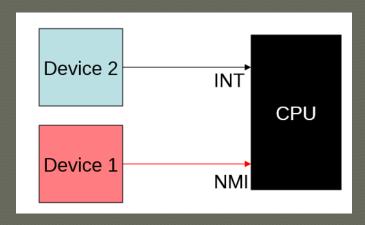

• Ex. If in user mode, shouldn't OS verify that file I'm writing/reading is mine?

#### • How would you implement?

- HW Interrupts: switch to kernel mode, save current state, service interrupt, restore state, switch back to user mode.
- Instructions that require OS verification: switch to kernel mode, verify access, run instruction, switch back to user mode.

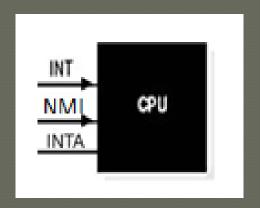

# Interrupts-HW-Asynchronous

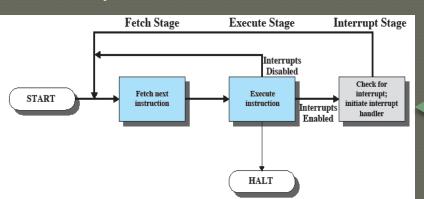

Device signals (interrupts) the CPU when it wants to be serviced

### Interrupts-HW

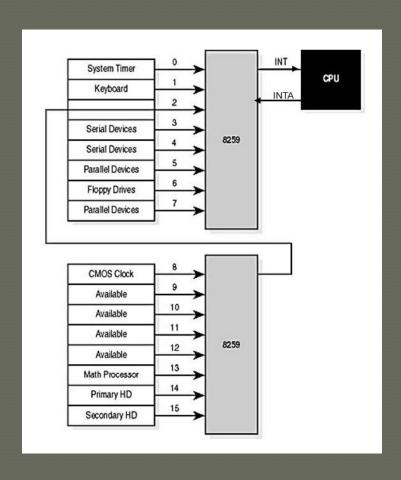

- Microprocessors have interrupt pins
  - INT interrupt the CPU (checked at completion of current assembly instruction, if interrupts enabled)
  - INTA Used by CPU to acknowledge interrupt, so INT can go low
  - NMI non maskable interrupt, cant turn this one off

# Interrupts-hardware

- 8259 (Programmable interrupt controller or PIC) relays up to 8 interrupt to CPU
- Devices raise interrupts by an 'interrupt request' (IRQ)
- CPU acknowledges and queries the 8259 to determine which device interrupted (int#)
- Priorities can be assigned to each IRQ line
- 8259s can be cascaded to support more interrupts
- How does OS handle particular interrupt?

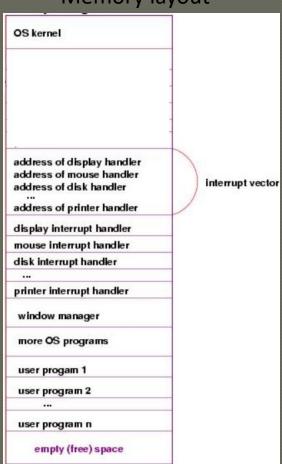

# Interrupts-IDT

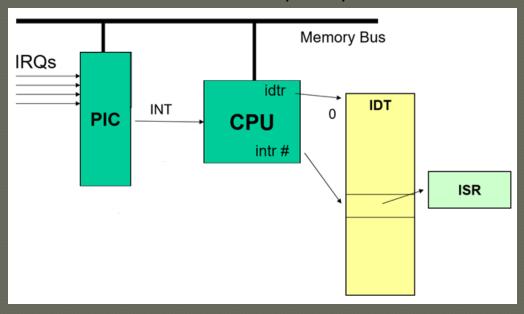

- OS sets up an Interrupt Descriptor Table (IDT) at boot (in memory, its base pointed to by IDT register(IDTR))
- Each entry is address of an interrupt handler (known as Interrupt Service Routine ISR)
- ISR is routine that handles a particular type of interrupt.
- Address of handler is IDT plus interrupt number

# Interrupts-Traps - Synchronous

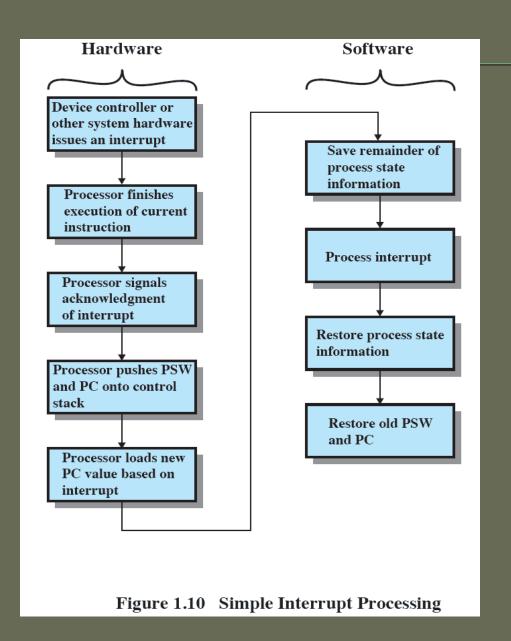

- Applications cannot perform privileged operations
- Must request OS to do it for them
- Switch from user to kernel mode

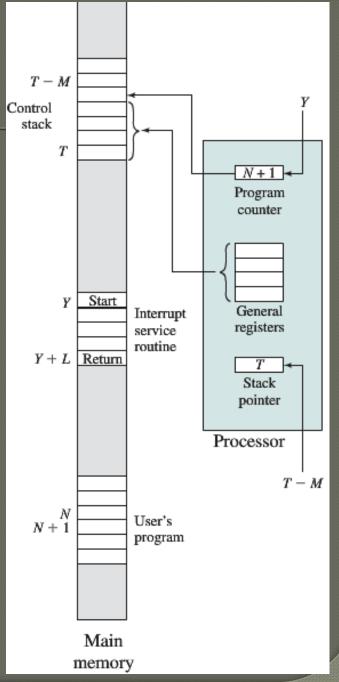

### Interrupts-Exceptions - Synchronous

- Program faults
  - Recoverable: page fault
  - Abort: divide by 0
- Applications cannot perform privileged operations
- Must request OS to do it for them
- Switch from user to kernel mode

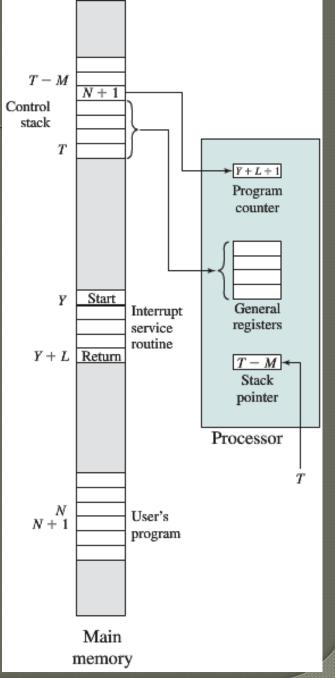

Simple Interrupt Processing

- What happens when CPU is disrupted by an interrupt?
  - Finish executing instruction N
  - { interrupt }
  - store registers, PC (size M) in control stack @ T
  - update stack pointer to T-M
  - execute interrupt instruction
     @ Y until finishing @ Y+L
  - load back top of control stack
  - continue executing @ N+1

- Multiple overlapping interrupts
  - An interrupt happens when another is being handled
  - 1. Disable interrupts (when handling an interrupt)
    - 2<sup>nd</sup> interrupt waits until 1<sup>st</sup> interrupt is handled
    - Strictly sequential
  - 2. Use a priority scheme
    - Interrupts can interrupt interrupt-handling...
    - ...but only if they have a higher priority; otherwise they wait
    - Hierarchical (by priority)

- Multiple overlapping interrupts
  - (approach 1) Interrupts disabled

- Multiple overlapping interrupts
  - (approach 2) Priority Scheme

- Major (conflicting) constraints
  - speed (access time), amount, cost
  - Memory must keep up with CPU (speed)
    - Faster access time = greater cost
  - Memory must satisfy data volumes (amount)
    - Greater capacity = smaller cost = slower access speed

Hierarchy going down

- cost decreases
- capacity increases
- access time increases
- frequency of access by CPU decreases
  - really? how does it happen?

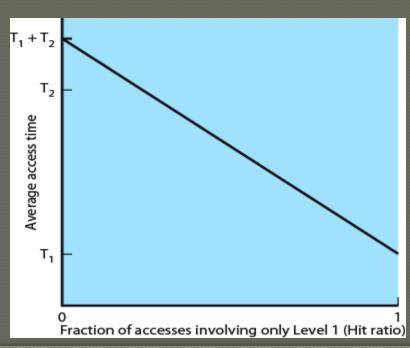

### Principle of Locality

- Why does frequency of access by CPU decrease?
  - Memory references (i.e., data) needed by CPU (i.e., the current set of instructions in a program) tend to cluster
    - e.g. array "a" being read in a loop
  - Data gets naturally clustered so that the percentage of accesses to each successively lower level is substantially less than that of the level above
- Eventually a set of data is replaced by another, but it's less frequent proportionally to the use within a set, which makes overhead bearable.

- Performance Example
  - 2 levels
    - T1 @ 0.1µs (1kb)
    - T2 @ 1μs (100kb)

faster but scarce

slower but plenty

- Performance Example
  - 2 levels
    - T1 @ 0.1µs (1kb) faster but scarce
    - T2 @ 1μs (100kb) slower but plenty
  - What's the average access time if...
    - 95% of data in T1 and 5% in T2?

#### Performance Example

- 2 levels
  - T1 @ 0.1μs (1kb) faster but scarce
  - T2 @ 1µs (100kb) slower but plenty µs
- What's the average access time if...
  - 95% of data in T1 and 5% in T2?
    - $0.95 * 0.1 \mu s + 0.05 * (0.1 \mu s + 1 \mu s) = 0.15 \mu s$
  - 5% of data in T1 and 95% in T2?

Looks in L1 first then L2

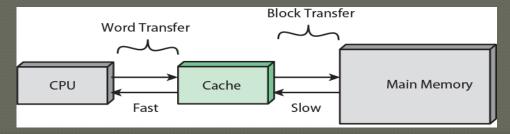

#### Performance Example

  - T1 @ 0.1μs (1kb) faster but scarce
  - T2 @ 1μs (100kb) slower but plenty
- What's the average access time if...
  - 95% of data in T1 and 5% in T2?
    - $0.95 * 0.1 \mu s + 0.05 * (0.1 \mu s + 1 \mu s) = 0.15 \mu s$
  - 5% of data in T1 and 95% in T2?
    - $0.05 * 0.1 \mu s + 0.95 * (0.1 \mu s + 1 \mu s) = 1.05 \mu s$
  - It's to our advantage to have frequently accessed data in faster memory locations

reason why caches exist

#### Cache

- Exploits the Principle of Locality
- Controlled by hardware (i.e., it is invisible to OS)
- Principles
  - Contains a copy of a portion of main memory
  - CPU checks cache for data
    - if found: use data
    - if not found: reads block of data from memory (where data is) and copies it into cache

- Conta
- CPU cl
  - if four
  - if not for copies i

In practice: several levels are common

Cache

data is) and

#### Cache Design

- Cache size
  - Even small caches decrease access times
- Cache block
  - Unit of data exchanged between cache and memory
    - Too small: less data than needed (overhead: constant exchanges).
    - Too large: more data than needed (overhead: storing unused data).
- Mapping function
  - Finds location in cache of a newly read block
  - If space needed, an existing block is replaced

#### Cache Design (2)

- Replacement algorithm
  - Least Recently Used (LRU) Algorithm
- Write policy
  - Indicates when a block is written back to memory
  - A) each time it is updated (with a new value)
    - Adds unnecessary writing overhead
  - B) each time it is replaced (with another block)
    - Minimizes write operations
    - Leaves memory in an obsolete state
      - ...which interferes with multi-processor operations accessing memory e.g., another program, buffered I/O, DMA

\* When the processor encounters an instruction relating to I/O, it executes that instruction by issuing a command to the appropriate I/O module

Three techniques are possible for I/O operations:

Programme d I/O Interrupt-Driven I/O Direct
Memory
Access (DMA)

What does the CPU do when finding an I/O (read/write) instruction?

- 1) Programmed I/O
  - CPU waits for completion of command and periodically checks the status of the I/O module until it determines the instruction is complete
    - 1. CPU sends I/O command to I/O module
    - If writing, CPU transfers data.
    - 2. CPU waits until I/O module completes command.
    - If reading, CPU transfers data
    - 3. CPU resumes execution
  - Extreme Inefficiency!

Remember the 1 sec verses 16 weeks example?

What does the CPU do when finding an I/O (read/write) instruction?

- 2) Interrupt-driven I/O
  - CPU keeps executing while I/O command is completed
    - 1. CPU sends I/O command to I/O module
    - If writing, CPU transfers data.
    - 2. CPU resumes execution.
    - 3. I/O module triggers an interrupt when command is done
    - If reading, CPU transfers data
    - 4. CPU resumes execution
  - No wait, but CPU still transfers data

- 2) Interrupt-driven I/O Drawbacks
  - Transfer rate is limited by the speed with which the processor can service a device
  - The processor is tied up in managing an I/O transfer since a number of instructions must be executed for each I/O transfer

What does the CPU do when finding an I/O (read/write) instruction?

- 3) Direct Memory Address (DMA)
  - Performed by a separate module on the system bus (DMA)
  - CPU keeps executing while I/O command is completed by DMA module
    - 1. CPU sends I/O command, memory address (where data is read or written), data size and I/O module to DMA
    - 2. CPU resumes execution.
    - 3. I/O module triggers an interrupt when command is done (including data transfer)
    - 4. CPU resumes execution
  - No wait & CPU doesn't transfer data (may have bus contention though)

#### 3) Direct Memory Address (DMA)

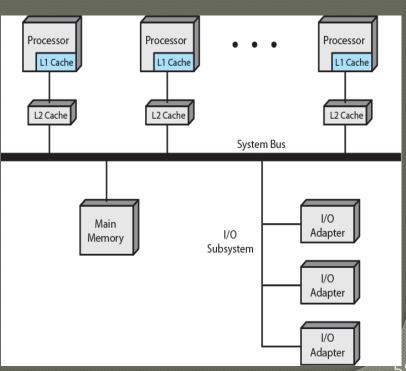

- Transfers the entire block of data directly to and from memory without going through the processor
  - processor is involved only at the beginning and end of the transfer
  - processor executes more slowly during a transfer when processor access to the bus is required
- More efficient than interrupt-driven or programmed I/O
- But DMA module uses bus, so CPU might have to wait

# Symmetric Multi-Processors

- A stand-alone computer system with:
  - 2+ similar processors:
    - capable of performing the same functions
  - which (physically):
    - are interconnected by a bus
    - share memory & I/O devices
  - are controlled by an OS that
    - provides interaction between processors and their programs (at the job, task, file, and data levels)

### Symmetric Multi-Processors

#### Advantages

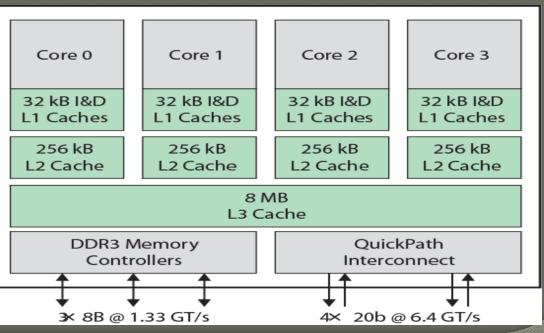

- Performance
  - can yield greater performance (if OS can handle work in parallel)
- Availability
  - failure of one processor does not halt the machine
- Scaling
  - additional processors result in a range of products of different price and performance

## Symmetric Multi-Processors

#### Multi-Core

- 2+ processors (cores) in 1 micro-chip
  - each core has all components of an independent processor (including 2 or 3 cache levels)
- Intel Core i7
  - 4-8 cores
  - 8 Mb L3 cache
  - Intel Iris Pro GPI
